

Reflection Seismic Data Processing

- General CMP processing sequence
- Highlights of some steps

- Reading:
 - › Sheriff and Geldart, Chapter 9

Reflection

Seismic Processing

- Objective - transform redundant reflection seismic records in the *time domain* into an interpretable *depth image*.
- Four general stages of data processing:
 - Data reduction and editing;
 - ♦ Transformation into conveniently computer-manageable form;
 - ♦ Removal of bad records;
 - Gathering;
 - ♦ CMP sorting;
 - Filtering in time and space;
 - ♦ Attenuation of noise;
 - Imaging
 - ♦ Final velocity and reflectivity image.

Seismic Processing Systems

- Seismic processing requires extensive support by software
 - Highly integrated
 - High performance
 - Interactive and batch processing
- Usually geared to a particular type of application
 - ◆ Mostly CMP reflection processing;
 - ◆ Land or marine, 2D or 3D.
- Commercial:
 - ◆ ProMAX (Landmark);
 - ◆ Omega (Western Geophysical, marine);
 - ◆ Echos (formerly Disco, Focus - Paradigm);
 - ◆ Vista (now Schlumberger/CGG)
- Universities:
 - ◆ Stanford Exploration Project;
 - ◆ Seismic UNIX (Colorado School of Mines);
 - ◆ FreeUSP (Amoco);
 - ◆ SIOSEIS (Scripps, marine);
 - ◆ Our own (IGeoS)

CMP Processing Sequence (initial data reduction)

- 1) Demultiplex, Vibroseis correlation, Gain recovery
 - ◆ Conversion from file formats produced by field data loggers into processing-oriented formats
 - SEG-Y, SEG-2.
 - ProMax, Focus, Omega, SU, Vista, etc., internal formats.
 - ◆ Often done in the field.
- 2) Field Geometry
 - ◆ Assignment of source-receiver coordinates, offsets, etc. in the *trace headers*.
- 3) Edit
 - ◆ Removal of bad traces (noisy channels, poorly planted geophones, channels contaminated by power line noise, etc.).

CMP Processing sequence (statics)

- 4) First arrival picking
 - ◆ May be semi-automatic or manual;
 - ◆ Required for generation of *refraction statics*; models and for designing the *mutes*.
- 5) Elevation statics
 - ◆ Based on geometry information, compensates the travel-time variations caused by variations in source/receiver elevations.
 - ◆ Transforms the records as if recorded at a common horizontal *datum* surface.
- 6) Refraction statics
 - ◆ Builds a model for the shallow, low-velocity subsurface;
 - ◆ Compensates travel-time variations caused by the shallow velocities.

CMP Processing Sequence (continued)

- 7) 'Top', 'bottom', and 'surgical' *mute*
 - ◆ Eliminates (sets amplitude=0) the time intervals where strong non-reflection energy is present:
 - ◆ First arrivals, ground roll, airwave.
- 8) Amplitude recovery
 - ◆ Compensates geometrical spreading;
 - ◆ Based on a simple heuristic relation.
- 9) Trace balance
 - ◆ Equalizes the variations in amplitudes caused by differences in *coupling*;
 - ◆ In true-amplitude processing, replaced with '*surface-consistent deconvolution*'.
- 10) Deconvolution or wavelet processing
 - ◆ Compresses the wavelet in time, attenuates reverberations.
 - ◆ Converts the wavelet to zero-phase for viewing
- 11) Gather, CMP sort
 - ◆ Often (in ProMax, Omega, Vista) done by using *trace lookup* tables instead of creating additional copies of the dataset.
- 12) Moveout (Radon, τ - p , f - k) filtering
 - ◆ Attenuates multiples, ground roll.

more steps will be continued later ...

Deconvolution

Deconvolving (inverse) Filter

- Objectives:
 - 1) Compress the wavelet into a sharper, minimum- or zero-phase shape;
 - 2) Remove predictable (short-period multiple) part of the signal;
 - 3) Broaden (flatten) the spectrum

■ This **improves resolution** of seismic images

More on deconvolution in **Filtering** section later...

Wavelet shaping

- Shape of the source wavelet is estimated from autocorrelation of the data
- Time-variant “spectral whitening” (flattening within an estimated bandwidth) is applied
- A filter is designed to convert the wavelet into **zero-phase**

Note the sharper resolution of layering after wavelet improvement

Migrated stack before wavelet processing

Migrated stack after wavelet processing

CMP Processing Sequence (continued)

13) Velocity analysis

- ◆ For each of the CMP gathers, determines the optimal *stacking velocity*.

14) Dip Moveout (DMO) correction

- ◆ Transforms the records so that the subsequent NMO+stack work well even in the presence of dipping reflectors.

15) Normal Moveout (NMO) correction

- ◆ Removes the effects of source-receiver separation from reflection records;
- ◆ Transforms the records as if recorded at normal incidence.

16) Residual statics

- ◆ Removes the remaining small travel-time variations caused by inaccurate statics or velocity model
- Steps 13-16 are usually iterated 3-5 times to produce accurate *velocity* and *residual statics* models.
 - ◆ This is because the success of velocity analysis depends on the quality of DMO/NMO and residual statics, and vice versa

more steps will be continued later, and now, let us consider velocity analysis, NMO and DMO ...

Normal Moveout (NMO) correction and stretching

- NMO correction transforms a reflection record at offset x into a normal-incidence ($x=0$) record:

$$t_0 = \sqrt{t^2(x) - \left(\frac{x}{V}\right)^2} \approx t(x) - \frac{1}{2t_0} \left(\frac{x}{V}\right)^2$$

“Stacking velocity”

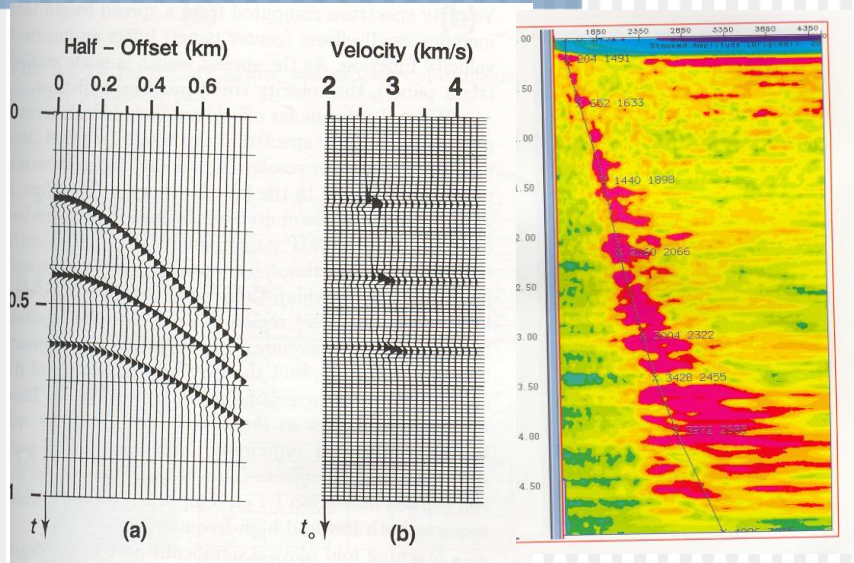

NMO correction

- NMO correction stretches shallower and slower reflections stronger
 - This affects the spectrum of the stack
 - This distortion is controlled during processing by setting a limit in relative stretch (typically $\sim 25\%$)

Velocity Analysis

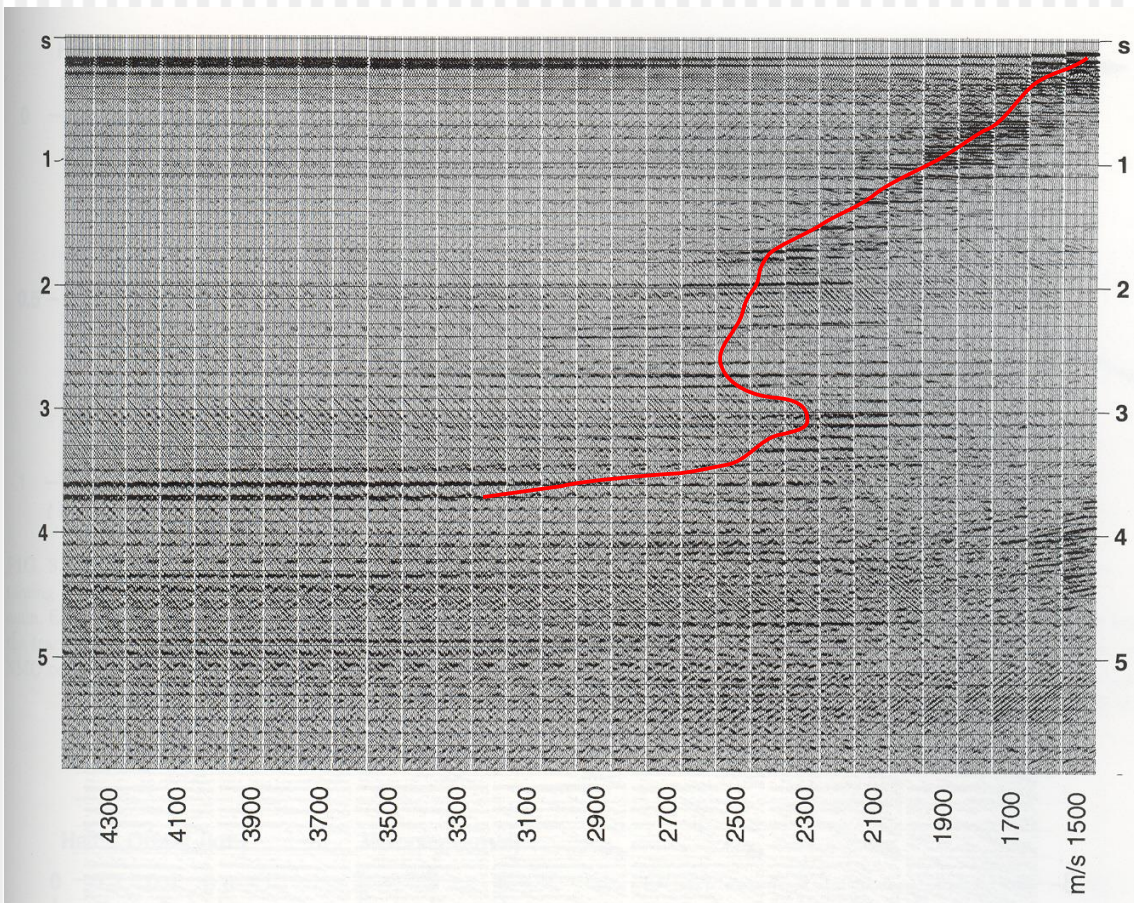

CMP gathers are stacked along trial-velocity hyperbolas and presented in time-velocity diagrams.

Velocity analysis

(Common-Velocity Stacks)

- Groups of CMP gathers are NMO-corrected (hyperbolas flattened) using a range of trial velocities and stacked.
- Velocities are picked at the amplitude peaks and best resolution in the stacks.

NMO → DMO → Migration

- DMO assists NMO by correcting for the time delay on an offset trace assuming zero dip.
- For a dipping reflector and a given source-receiver pair, DMO shifts the time of the NMO-corrected reflection and its position to those of the correct zero-offset trace. Migration finally moves it to the correct subsurface location of the reflection.

CMP Processing Sequence (continued)

17) CMP Stack

- ◆ Produces a *zero-offset section*;
- ◆ Utilizes CMP redundancy to increase the *Signal/Noise ratio*.
- ◆ Can employ various normalization ideas, e.g., *diversity stack*

18) Migration

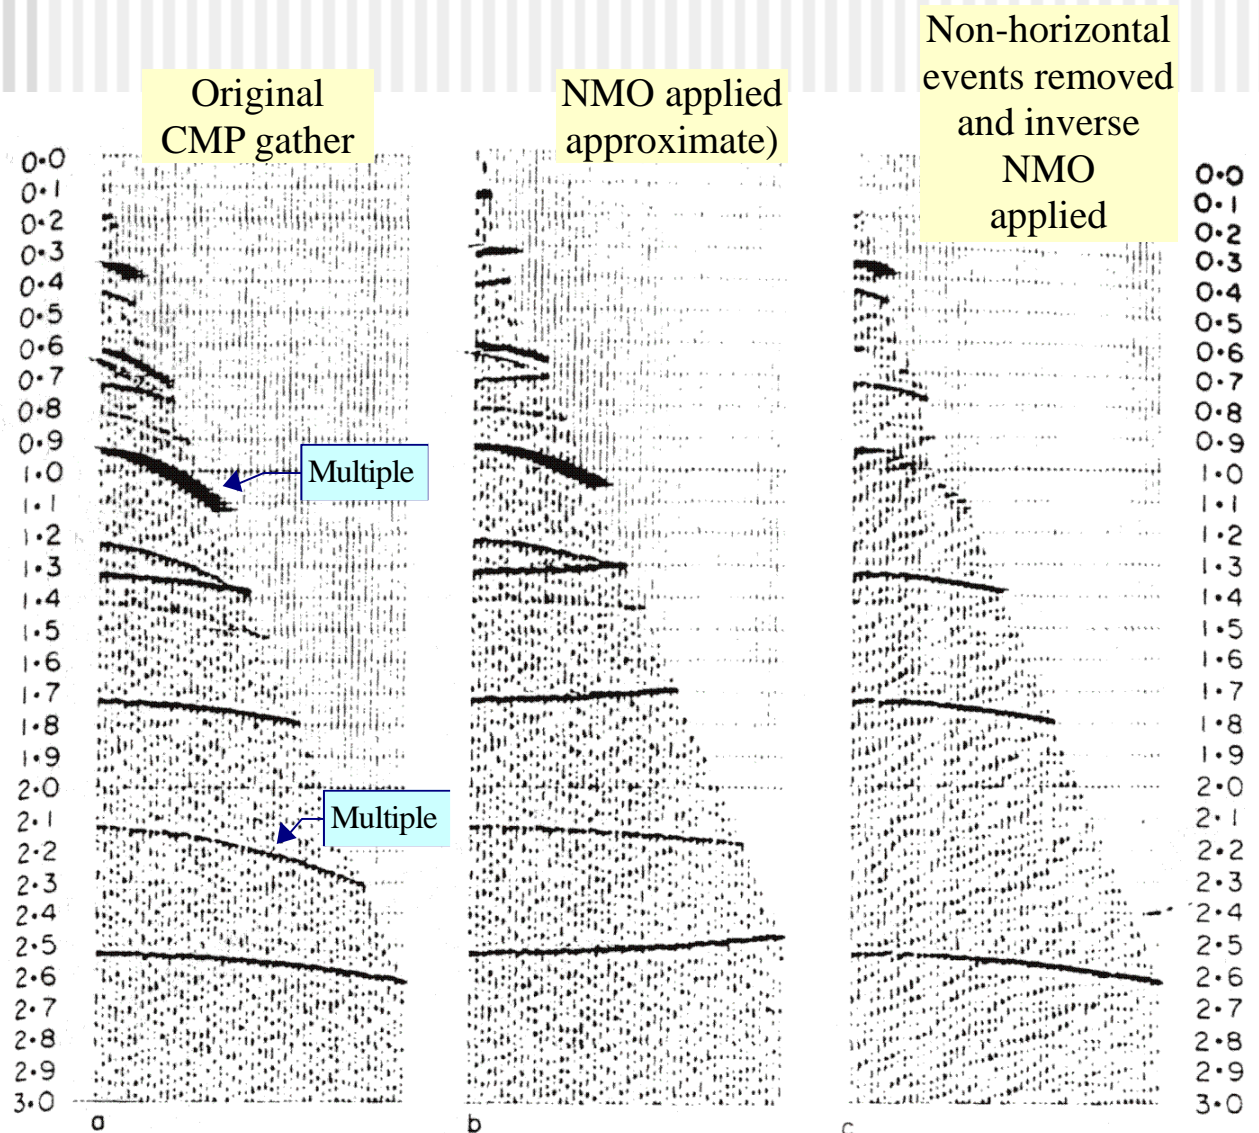

- ◆ Transforms the zero-offset *time* section into a depth image;
- ◆ Establishes correct extents and dips of the reflectors.

19) Frequency filtering and display

- ◆ Attenuates noise
- ◆ Provides best display for interpretation

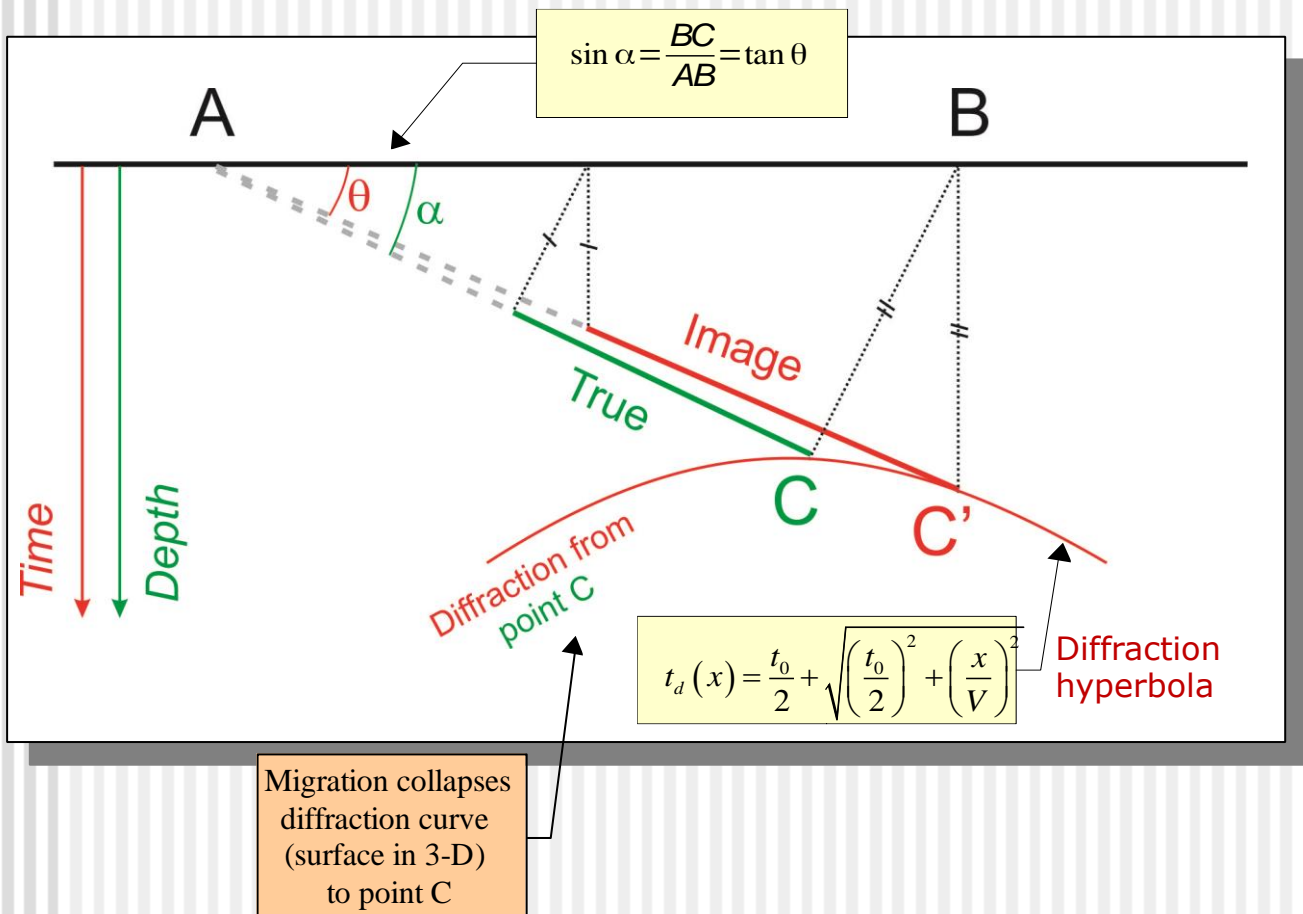

Moveout ($f-k$, $\tau-p$) filtering

- Removes coherent events with undesired moveouts

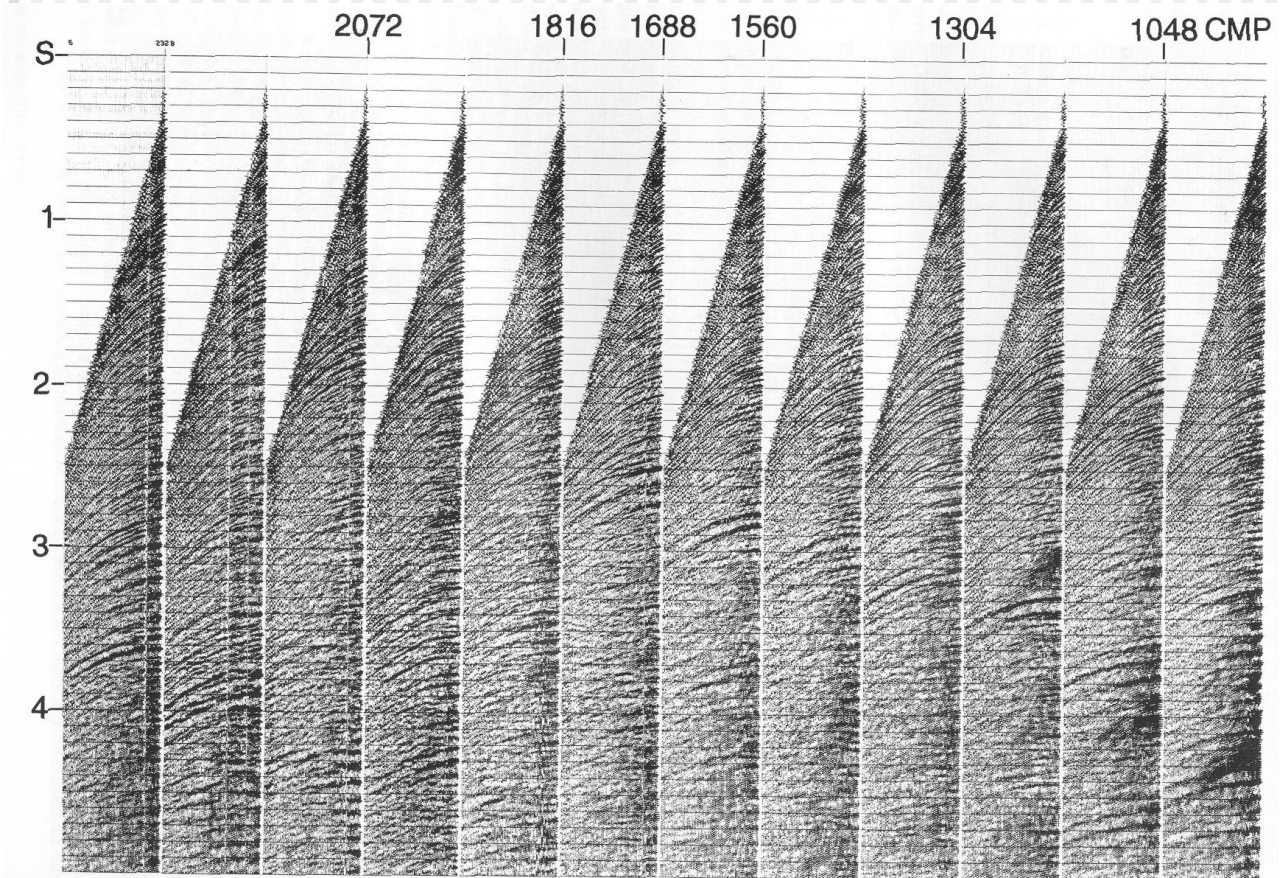

Migration

- A simplified variant of '*inversion*' (without changing amplitudes)
 - ◆ Inverts 'time section' for true 'depth image'
- Establishes true positions (AC in plot) and dips (α) of reflectors.
- Collapses diffractions

Example: CMP gathers

Example:

CMP gathers after NMO correction

- Note some imperfectly corrected reflections because of stacking velocities being dependent on conflicting dips
- Also, multiples are “frowning” (under-corrected), because stacking velocities for multiples are typically lower than for primary reflections at the same depth.

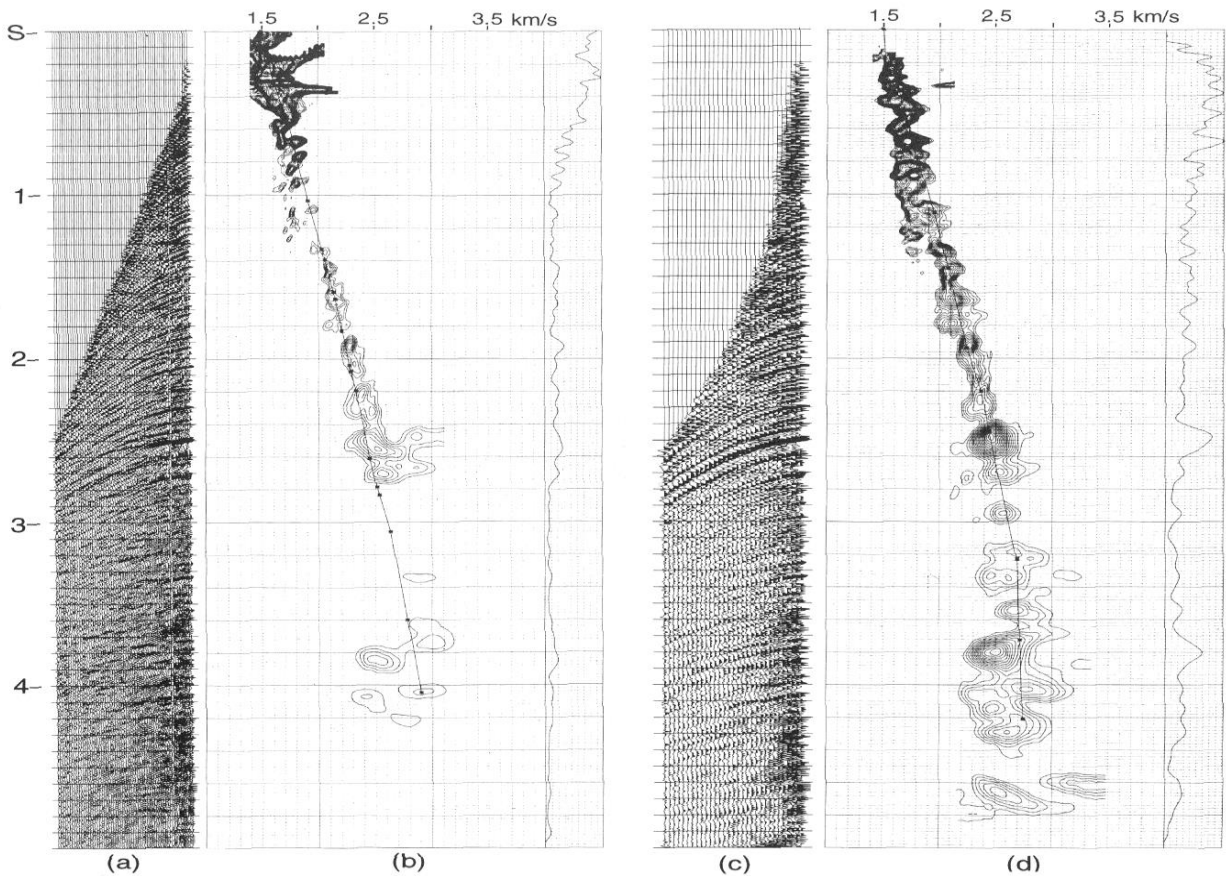

Example:

CMP gathers after NMO+DMO corrections

- Note that after DMO, the problem of conflicting dips is resolved
- Some multiples are still “frowning”, but this means that they will be removed by stacking

Example: Velocity analysis

Without DMO

With DMO

- Note the improved accuracy of velocity picking and increased semblance values after DMO

Example:

NMO (with DMO) stack

Zero-offset section

- Note the criss-crossing reflections and incorrect positions of dipping structures in the time section before migration

Example:

Final migrated stack

- Note that structures, positions, and dips are finally correct
